

WHAT IS CLAIMED IS:

1. An image data converting apparatus for converting first compressed image data to second compressed image data more compressed than the first compressed image data, said first compressed image data being interlaced-scan data that has been compressed by orthogonal transform and motion compensation, and said second compressed data being serial-scan data, said apparatus comprising:

image data decoding means for decoding the first compressed image data by using only lower m th-order orthogonal transform coefficients included in n th-order orthogonal transform coefficients (where $m < n$), in both a vertical direction and a horizontal direction in the first compressed image data;

scan-converting means for converting interlaced-scan data output from the image data decoding means to serial-scan data; and

image data encoding means for encoding the serial-scan data, thereby generating the second compressed image data.

2. The apparatus according to claim 1, wherein the first compressed image data is MPEG2-image compressed data containing eighth-order discrete cosine transform coefficients in both the vertical direction and the horizontal direction, the image data decoding means is MPEG2-image data decoding means for decoding the MPEG2-image compressed data in both the vertical direction and the horizontal direction, by using only lower fourth-order coefficients included in eighth-order discrete cosine transform coefficients, and the image data encoding means is

MPEG4-image encoding means for encoding the serial-scan data, thereby generating MPEG4-image compressed data.

3. The apparatus according to claim 2, which further comprises picture-type determining means for determining the code type of each frame in the interlaced-scan MPEG2-image compressed data, outputting data about an intra-image encoded image/forward prediction encoded image and discarding data about a bi-directional prediction encoded image, thereby to convert a frame rate, and in which an output of the picture-type determining means is input to the MPEG2-image data decoding means.

4. The apparatus according to claim 3, wherein the MPEG2-image data decoding means decodes only the intra-image encoded image/forward prediction encoded image.

5. The apparatus according to claim 2, wherein the MPEG2-image data decoding means comprises variable-length decoding means, and the variable-length decoding means performs variable-length encoding on only the discrete cosine transform coefficients required in a discrete cosine transform, in accordance with whether the macro block of the input MPEG2-image compressed data is of field-discrete cosine transform mode or fame-discrete cosine transform mode.

6. The apparatus according to claim 2, wherein the MPEG2-image data decoding means comprises compression inverse discrete-cosine transform means of field-discrete cosine transform mode, the compression inverse discrete-cosine

transform means extracts only the lower fourth-order coefficients included in the eighth-order discrete cosine transform coefficients, in both the vertical direction and the horizontal direction, and then performs fourth-order inverse discrete cosine transform on the lower fourth-order coefficients extracted.

7. The apparatus according to claim 6, wherein the inverse cosine transform is carried out in both the horizontal direction and the vertical direction, by a method based on a predetermined fast algorithm.

8. The apparatus according to claim 2, wherein the MPEG2-image data decoding means comprises compression inverse discrete-cosine transform means of frame-discrete cosine transform mode, the compression inverse discrete-cosine transform means extracts only the lower fourth-order coefficients included in the eighth-order discrete cosine transform coefficients, in the horizontal direction, and then performs fourth-order inverse discrete cosine transform on the lower fourth-order coefficients extracted, and field-discrete cosine transform is performed in the vertical direction.

9. The apparatus according to claim 8, wherein the inverse cosine transform is carried out in both the horizontal direction and the vertical direction, by a method based on a predetermined fast algorithm.

10. The apparatus according to claim 8, wherein the compression inverse discrete-cosine transform means of frame-discrete cosine transform mode performs the inverse discrete cosine transform by using only $(4 \times 4 + 4 \times 2)$ th-order coefficients

included in (4×8) th-order discrete cosine transform coefficients input to achieve the field-discrete compression inverse discrete cosine transform, while replacing the remaining coefficients by 0s, thus discarding the remaining coefficients.

11. The apparatus according to claim 2, wherein the MPEG2-image data decoding means comprises motion-compensating means, and the motion-compensating means performs 1/4-precision pixel interpolation in both the horizontal direction and the vertical direction, in accordance with a motion vector contained in the input MPEG2-image compressed data.

12. The apparatus according to claim 11, wherein the motion-compensating means performs 1/2-precision pixel interpolation in the horizontal direction by using a twofold interpolation digital filter and then performs the 1/4-precision pixel interpolation by means of linear interpolation.

13. The apparatus according to claim 11, wherein the motion-compensating means performs 1/2-precision pixel interpolation in a field, as vertical interpolation by using a twofold interpolation digital filter, and then performs the 1/4-precision pixel interpolation in the field by means of linear interpolation, when macro block of the input MPEG2-image compressed data is of field prediction mode.

14. The apparatus according to claim 11, wherein the motion-compensating means performs 1/2-precision pixel interpolation in a field, as vertical interpolation by using a twofold interpolation digital filter, and then performs the 1/4-precision pixel interpolation in the field by means of linear interpolation, when macro block of the

input MPEG2-image compressed data is of frame prediction mode.

15. The apparatus according to claim 11, wherein the motion-compensating means uses, as the twofold interpolation digital filter, a half-band filter.

16. The apparatus according to claim 11, wherein the MPEG2-image data decoding means comprises storage means for storing pixel values, and the motion-compensating means calculates coefficients equivalent to a sequence interpolating operations and applies the coefficients, thereby to perform motion compensation on the pixel values read from the storage means in accordance with the motion vector contained in the input MPEG2-image compressed data.

17. The apparatus according to claim 11, wherein, when pixel values outside an image frame are required to achieve twofold interpolation, the motion-compensating means performs mirror process or hold process, thereby generating as many virtual pixel values as the taps provided in a filter in order to accomplish , before performing the motion compensation.

18. The apparatus according to claim 17, wherein the motion-compensating means performs the mirror process or the hold process in units of fields.

19. The apparatus according to claim 2, wherein the scan-converting means preserves a first field or a second field of the interlaced-scan image data output from the MPEG2-image data decoding means, discards the other of these two fields, and performs twofold up-sampling on preserved pixel values, thereby converting the interlaced-scan data to serial-scan data.

09755852.014901

20. The apparatus according to claim 2, wherein the MPEG2-image data decoding means has the function of encoding only a region composed of one or more macro blocks that surround an object in an intra-image encoded image/forward prediction encoded image.

21. The apparatus according to claim 2, further comprising motion-vector synthesizing means for generating a motion vector value corresponding to the image data subjected to scan conversion, from the motion vector data contained in the input MPEG2-image compressed data.

22. The apparatus according to claim 21, further comprising motion-vector detecting means for detecting a high-precision motion vector from the motion vector value generated by the motion-vector synthesizing means.

23. An image data converting method of converting first compressed image data to second compressed image data more compressed than the first compressed image data, said first compressed image data being interlaced-scan data that has been compressed by orthogonal transform and motion compensation, and said second compressed data being serial-scan data, said method comprising the steps of:

decoding the first compressed image data by using only lower m th-order orthogonal transform coefficients included in n th-order orthogonal transform coefficients (where $m < n$), in both a vertical direction and a horizontal direction in the first compressed image data;

converting interlaced-scan data output from the image data decoding means to

serial-scan data; and

encoding the serial-scan data, thereby generating the second compressed image data.

24. The method according to claim 23, wherein the first compressed image data is MPEG2-image compressed data containing eighth-order discrete cosine transform coefficients in both the vertical direction and the horizontal direction, the step of the decoding the first compressed image data is to decode the MPEG2-image compressed data in both the vertical direction and the horizontal direction, by using only lower fourth-order coefficients included in eighth-order discrete cosine transform coefficients, and the step of encoding the serial-scan data is to encode the serial-scan data, thereby generating MPEG4-image compressed data.

25. The method according to claim 24, wherein the code type of each frame in the interlaced-scan MPEG2-image compressed data is determined, data about an intra-image encoded image/forward prediction encoded image is output in accordance with the code type determined, data about a bi-directional prediction encoded image is discarded thereby to convert a frame rate, and the MPEG4-image compressed data is generated from the frame rate converted..

26. The method according to claim 25, wherein only the intra-image encoded image/forward prediction encoded image is decoded in the step of decoding the MPEG2-image compressed data.

27. The method according to claim 24, wherein in the process of decoding

the MPEG2-image compressed data, variable-length decoding is performed on only the discrete cosine transform coefficients required in a discrete cosine transform, in accordance with whether the macro block of the input MPEG2-image compressed data is of field-discrete cosine transform mode or fame-discrete cosine transform mode.

28. The method according to claim 24, wherein in the process of decoding the MPEG2-image compressed data, inverse discrete-cosine transform means of field-discrete cosine transform mode is performed by extracting only the lower fourth-order coefficients included in the eighth-order discrete cosine transform coefficients, in both the vertical direction and the horizontal direction, and then by performing fourth-order inverse discrete cosine transform on the lower fourth-order coefficients extracted.

29. The method according to claim 28, wherein the inverse cosine transform is carried out in both the horizontal direction and the vertical direction, by a method based on a predetermined fast algorithm.

30. The method according to claim 24, wherein in the process of decoding the MPEG2-image compressed data, compression inverse discrete-cosine transform means of frame-discrete cosine transform mode is performed by extracting only the lower fourth-order coefficients included in the eighth-order discrete cosine transform coefficients and then fourth-order inverse discrete cosine transform is performed on the lower fourth-order coefficients extracted, in the horizontal direction, and field-discrete cosine transform is performed in the vertical direction.

31. The method according to claim 30, wherein the inverse cosine transform is carried out in both the horizontal direction and the vertical direction, by a method based on a predetermined fast algorithm.

32. The method according to claim 30, wherein in the compression inverse discrete-cosine transform of frame-discrete cosine transform mode, only $(4 \times 4 + 4 \times 2)$ th-order coefficients included in (4×8) th-order discrete cosine transform coefficients input are used to achieve inverse cosine transform, while replacing the remaining coefficients by 0s.

33. The method according to claim 24, wherein in the motion compensation performed in the process of decoding the MPEG2-image compressed data, 1/4-precision pixel interpolation is carried out in both the horizontal direction and the vertical direction, in accordance with a motion vector contained in the input MPEG2-image compressed data.

34. The method according to claim 33, wherein in the process of motion compensation, 1/2-precision pixel interpolation is performed in the horizontal direction by using a twofold interpolation digital filter and then 1/4-precision pixel interpolation is performed by means of linear interpolation.

35. The method according to claim 33, wherein in the process of motion compensation, 1/2-precision pixel interpolation is performed in a field, as vertical interpolation, by using a twofold interpolation digital filter, and then 1/4-precision pixel interpolation is performed in the field by means of linear interpolation, when

macro block of the input MPEG2-image compressed data is of field prediction mode.

36. The method according to claim 33, wherein in the process of compensating motion, 1/2-precision pixel interpolation is performed in a field, as vertical interpolation, by using a twofold interpolation digital filter, and then the 1/4-precision pixel interpolation is performed in the field by means of linear interpolation, when macro block of the input MPEG2-image compressed data is of frame prediction mode.

37. The method according to claim 33, wherein in the process of compensating motion, a half-band filter is used as the twofold interpolation digital filter, to perform the interpolation.

38. The method according to claim 33, wherein in the process of decoding the MPEG2-image compressed data, pixel values are stored, and in the process of performing motion compensation, coefficients already calculated and equivalent to a sequence interpolating operations are applied, thereby to perform motion compensation on the pixel values stored, in accordance with the motion vector contained in the input MPEG2-image compressed data.

39. The method according to claim 33, wherein, when pixel values outside an image frame are required to achieve twofold interpolation, mirror process or hold process is performed, thereby generating as many virtual pixel values as the taps provided in a filter in order to accomplish the motion compensation.

40. The method according to claim 39, in the process of performing the

motion compensation, the mirror process or the hold process is carried out in units of fields.

41. The method according to claim 24, wherein in the process of performing the scan conversion, a first field or a second field of the interlaced-scan image data is preserved, and the other of these two fields is discarded, and twofold up-sampling is performed on preserved pixel values, thereby converting the interlaced-scan data to serial-scan data, said first and second fields being ones contained in the MPEG2-image compressed data that has been decoded.

42. The method according to claim 24, wherein only a region composed of one or more macro blocks that surround an object in an intra-image encoded image/forward prediction encoded image is encoded in the process of decoding the MPEG2-image compressed data.

43. The method according to claim 24, wherein a motion vector value corresponding to the image data subjected to scan conversion is synthesized from the motion vector data contained in the input MPEG2-image compressed data.

44. The method according to claim 43, wherein a high-precision motion vector is detected from the motion vector value that has been synthesized.
